The token moves.
The underlying stays at DTC.

BINARY / BUILD / 14 NOV 2026
The architecture separates movement from custody.

ONE ASSET / TWO COORDINATED LAYERS

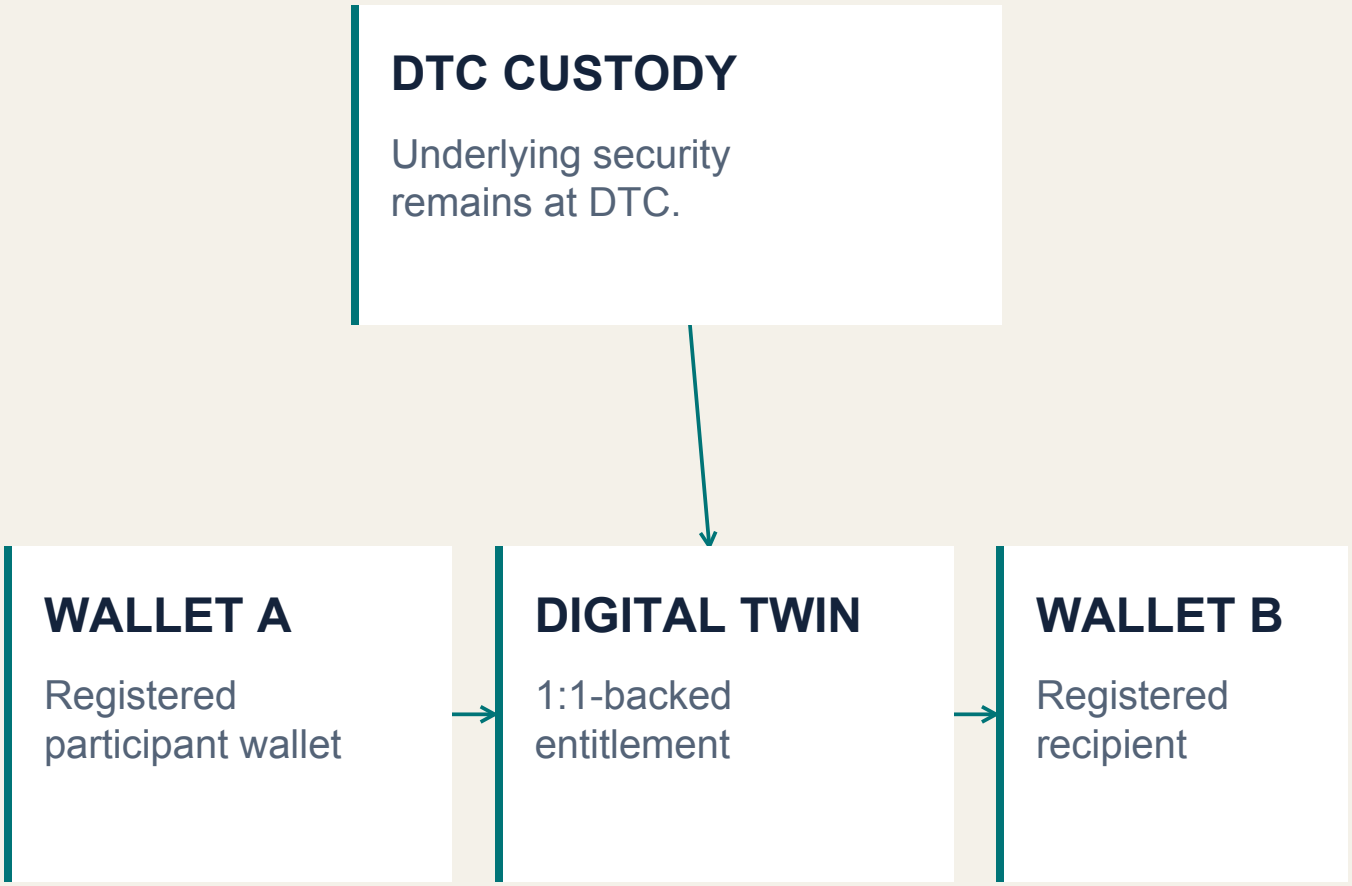

Keep the anchor.
Change the movement layer.

The tokenized entitlement carries legal and economic rights; it is not a decorative receipt.

> **A new rail does not require a new custody anchor.**

One asset.
Two layers.

The security remains in DTC custody. Its 1:1-backed digital twin can move between registered wallets.

A transfer changes the recorded entitlement. It does not move the underlying security out of DTC custody.

Mobility is added at the entitlement layer—not the custody layer.

The entitlement changes hands. The anchor does not.

A transfer changes who holds the tokenized right while the underlying and its 1:1 relationship remain fixed.

BEFORE

Wallet A holds the entitlement

Underlying security remains at DTC.

Digital twin is 1:1 backed.

Wallet A is the registered holder.

AFTER

Wallet B holds the entitlement

Underlying security still remains at DTC.

The 1:1 relationship is maintained.

Wallet B becomes the registered holder.

Rights move with the tokenized entitlement; the custody location of the underlying does not.

> **The token is consequential without duplicating the underlying.**

Production exists today. On two current rails.

DTCC reported production activity in July and launched DTS in October on Canton and its private Besu environment.

01 **Canton**

Current production environment reported by DTCC.

02 **Private Besu**

Current production environment operated by DTCC.

03 **Registered wallets**

Current transfers remain inside the participant boundary.

04 **Solana**

Planned connection; expected availability in H2 2027.

No cross-network interoperability or live Solana link is established.

> **Current production is real. Solana production is not yet evidenced.**

Public rail ≠ public access.

A network can be public while the service using it keeps identity, eligibility and wallet registration at the door.

PUBLIC RAIL / PLANNED

Solana H2 2027 target

Shared network infrastructure.

Connection announced, not yet observed.

Final implementation remains unpublished.

GOVERNED ACCESS / CURRENT

DTS participant boundary

Eligible DTC participants.

DTC-registered wallets.

Controlled holders and recipients.

Applying today's permission boundary to the planned Solana connection is an inference, not observed deployment evidence.

Network openness and service permissioning are separate controls.

The mechanism is evidenced. The upside is not measured.

A first transaction can prove that a rail works. Repeated measurements are needed to prove cost or liquidity gains.

BOUNDARY	SUPPORTED NOW	STILL OPEN
MECHANISM	DTC custody; 1:1 entitlement; registered wallets	Final Solana implementation
PRODUCTION	Canton + private Besu	Attributable completed Solana event
OUTCOME	A controlled movement layer exists	Lower realized cost or greater liquidity

No attributable completed DTS Solana transaction, official program or stated production cluster appears in the frozen reviewed record.

> **Architecture first. Economics later—and with a baseline.**

The sources.
And the boundary.

Primary DTCC material checked 14 November 2026. Tap a title to open it.

S1 **DTCC: Tokenization Service Goes Live**
2026-10-28 | Launch, rights and current networks.

S2 **DTCC: Tokenization Service**
checked 2026-11-14 | 1:1 backing and wallet boundary.

S3 **DTCC: Production Activity**
2026-07-15 | Canton and private Besu production.

S4 **DTCC: Planned Solana Connection**
2026-11-12 | H2 2027 target; not a live event.

General learning and API references were also checked; both predate the Solana announcement and do not evidence a completed integration.

> **Current rails are observed. Solana remains a dated plan.**
