The clock moved. The quote did not.

USDY began accruing price by the second. A one-token USDC quote still looked frozen.

THREE CLOCKS, ONE VISIBLE NUMBER

More precise accounting. Same visible quote.

The quote is a gross arithmetic illustration, not an executed redemption or holder return.

> **A moving value can disappear inside a coarser display unit.**

Old clock.
New clock.

Both systems represent accumulation. They place it on different points of the timeline.

LEGACY SCHEDULE

One daily step

Flat between scheduled prices

Books a full-day increase at 00:00 UTC

About $0.00011623 at the tested boundary

CONTINUOUS ORACLE

Elapsed seconds

Calculates at request time

Accrues through intraday, weekend and holiday time

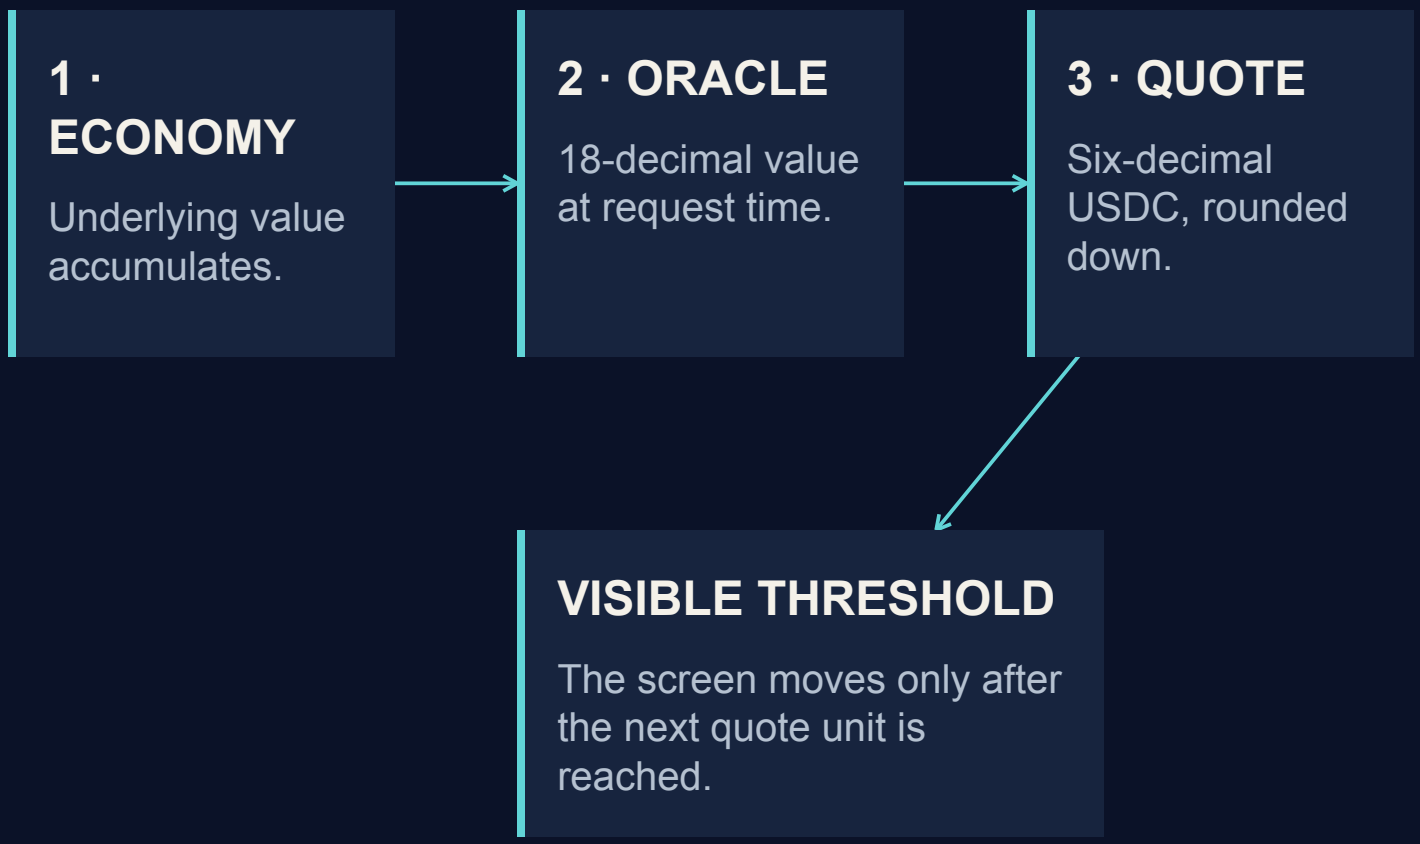

About $0.000000001345 in the tested second

The legacy schedule is a comparison after cutover, not the official current-price path.

The change is about when accrued value enters the current price.

Three clocks feed one displayed balance.

Economic accumulation, oracle precision and quote precision are separate layers.

Refresh cadence and quantity can add further display thresholds outside this simplified map.

Do not infer the first two clocks from the last one alone.

One second moved. Six decimals hid it.

The high-precision price changed across midnight while the gross one-token quote did not.

1.152259433 → 1.152259434 USDY price

1.152259 → 1.152259 USDC quote

Elapsed time → 1 second

Value increase → ≈ $0.000000001345 / USDY

Transactions → 0

> **The unchanged display is a rounding result, not proof of zero accrual.**

Build the precision stack on purpose.

A correct oracle value can still become a misleading interface if the downstream rules stay implicit.

01

1 · Timestamp

State which request time the price represents.

02

2 · Precision

Keep high precision through intermediate math.

03

3 · Rounding

Define direction, decimals and quote asset.

04

4 · Boundary test

Test actual quantities across cutovers and thresholds.

05

5 · Display copy

Do not label an unchanged rounded quote as no accrual.

Historical prices require a separate method from the current-price wrapper.

Timestamp, intermediate precision and final rounding each need an owner.

The mechanism is clear. The proceeds are not.

The exercise tested pricing arithmetic. It did not execute a holder transaction.

SUPPORTED NOW

Read-only calculation

- Current-price routing and cutover
- One-second and weekend arithmetic
- Six-decimal gross quote behavior

STILL UNKNOWN

Executed outcome

- Holder eligibility and applicable fees
- Service availability, liquidity and limits
- Settlement and realized proceeds

No wallet, signature, approval, redemption, transaction or capital allocation was used.

Keep a precise calculation separate from an unmeasured financial outcome.

A frozen quote can hide a moving clock.

Economic value can accumulate while the oracle calculates continuously and the display waits for its next rounded unit.

SURFACE QUESTION

Did the displayed quote change?

Which clock moved, and where was it rounded?

Test the exact quantity, quote asset and timestamp boundary before calling a financial display continuous.

Read-only evidence · Gross arithmetic · Net proceeds UNKNOWN

> **Precision is a stack, not a badge.**
